**February 17-19, 2010**

**Washington DC**

## **USER COST FOR RENTS OF DWELLINGS IN THE WEST BALKAN COUNTRIES.**

Below are the relevant parts of an OECD-EFTA report on “MEASURING THE NON-OBSERVED ECONOMY IN WESTERN BALKAN COUNTRIES The final report on Phase II prepared for EFTA by the OECD and Statistics Norway.” The project ran from 2004 to 2008

### **User cost estimates of imputed rents for owner-occupiers**

52. Strictly speaking, imputed rents for owner occupied dwellings are not part of the NOE, but it is important that they are estimated in line with international recommendations if measures of GDP exhaustiveness are to be comparable across countries. The standard method of estimating rents of owner occupiers is to stratify the housing stock by size, facilities and location and impute rents for owner occupiers in line with rents actually paid for similar dwellings. In WBC this method cannot be applied because their rental markets are small and limited to the capital city or principal urban centres, the dwellings rented are not typical of the total housing stock, the tenants are usually foreigners paying rents that cannot be regarded as representative.

53. When the standard procedure cannot be used, expenditure on dwellings is estimated by the user cost approach. The user cost approach consists of estimating each of the costs that the owners of the dwelling would need to take into account in fixing a market rent if they decided to rent their dwellings to other people rather than to live in them themselves. These costs are:

- Intermediate consumption,
- Other taxes on production,
- Consumption of fixed capital,
- Net operating surplus.

54. Intermediate consumption consists of expenditures on routine maintenance and repairs plus insurance premiums less insurance claims. Other taxes on production are taxes on dwellings and the land on which they are located. These taxes are often called “property taxes”. Consumption of fixed capital is the decline in the value of dwellings as they get older due to wear and tear and obsolescence. It is measured only for buildings since the land on which they are located does not depreciate. The net operating surplus is an estimate of the interest the owners could have received if they had invested in a financial asset instead of purchasing a dwelling. It is calculated as a percentage of the current market dwellings of the dwelling and the land on which they are situated.

55. The guidelines and table templates provided to WBC for the user cost approach can be found in Annex 4.

56. The chief problem in applying the user cost method is that it requires an estimate of the stock of dwellings valued at current market prices. This is normally obtained by a Perpetual Inventory Model (PIM) but WBC do not have sufficiently long time series to apply the PIM. As an alternative they have estimated the value of the stock of dwellings using information on the numbers and size of dwellings from a recent housing or population census and information on the price per square metre of new dwellings. These prices are then reduced – usually by about one half – to take account of the fact that the dwelling stock consists of new dwellings, dwellings that are at the end of their useful lives and dwellings of all vintages in between.

57. Table 9 shows the main data sources and assumptions underlying the user cost estimates of imputed dwelling services in WBC. All countries used the standard worksheets in Annex 4 to produce these estimates and most countries have made similar assumptions. For example, dwellings are all assumed to have average service lives of between 70 and 80 years. And capital consumption is estimated at 1.6% of the current market value of the dwelling stock.

58. The last column of Table 9 shows the user cost estimates of imputed rents as a percentage of GDP. These range from 5.8 in Bosnia-Herzegovina to 10.6 in FYR of Macedonia. This range looks rather large given the similarities of the housing stock in WBC.

**Table 9. User cost estimates of imputed rents of owner occupiers**

Country/Entity (Agency)	Base year for stock of dwellings	Is the dwelling stock stratified by region or quality of dwelling?	Valuation of housing stock	Source for intermediate consumption	Net insurance premiums	Other taxes on production	Net operating surplus as % of current market value of dwellings and land)	Consumption of fixed capital (annual depreciation as % of current market value of dwellings)	Service lives of dwellings	Are the user cost estimates included in official national accounts?	User cost estimates of imputed rent as % of GDP for latest year available
<b>Albania (INSTAT)</b>	2001 Population and housing census	Separate calculations for four regions	Construction experts	LSMS	1% of total intermediate consumption	Zero	2.5%	1.6%	?	No	?
<b>Bosnia-Herzegovina (BHAS)</b>	2004 HBS	Stratified by facilities	Construction experts	HBS	1% of total intermediate consumption	Zero	3.0% urban 2.0% rural	1.6%	80 years urban 70 years other	Yes	5.8
<b>Croatia (CBS)</b>	2001 Population census	Stratified by facilities	PIM stock estimates using PPP prices	HBS smoothed	Supervisory Agency for Insurance Companies	Tax authority data base	2.5%	2.27% and 1.16%	80	No	8.1
<b>Kosovo under UNSCR 1244 (SOK)</b>	Tax data base of Ministry of Finance	Separate calculations for old/new rural/urban dwellings by municipality	Price per m <sup>2</sup> from construction companies	HBS	Zero	Ministry of Finance	2.5%	1.6%	70 years	No	?
<b>FYR of Macedonia (SSORM)</b>	2002 Population census	Separate calculations for rural and urban dwellings	Construction experts	HBS	Zero	0.05% of market value	2.5%	1.6%	70 years	No	10.6
<b>Montenegro (MONSTAT)</b>	2003 Census of population and dwellings	Separate calculations for four regions	Construction surveys, newspaper advertisements, real estate agents	HBS	Data from insurance companies	Poll of MONSTAT staff	2.28 to 2.42% depending on mortgage rates over period	1.6%	72 years	Yes	9.4
<b>Serbia (RSOS)</b>	2002 Census of population and dwellings	Separate calculations for rural and urban dwellings by region	Construction surveys, HBS, ad hoc survey and real estate agencies.	RSOS Construction Statistics Department	Data from National Bank of Serbia and a large insurance company	Tax authority data base	2.09 to 2.29% depending on mortgage rates over period	1.6%	75 years	Yes	8.4

59. In the user cost estimates of Phase I, the share of intermediate consumption in output varied considerably between countries suggesting that some of them may have included expenditures under regular repair and maintenance that should have been included under final consumption expenditure or under capital expenditure. In Phase II, participating statistical agencies were asked to pay particular attention to what they included under regular repair and maintenance when they were refining their Phase I user cost estimates. Table 10 compares the shares of intermediate consumption in output in Phase I with the corresponding shares in Phase II. The Phase II shares are much closer together than the Phase I shares indicating that participating agencies have carefully scrutinised their expenditures on repairs and maintenances before allocating them to intermediate consumption. Even so, the shares for Montenegro and Serbia appear on the low side.

<b>Table 10. User cost estimates: Intermediate consumption as per cent of output in Phase I and Phase II</b>		
<b>Country/Entity</b>	<b>Phase I</b>	<b>Phase II</b>
Albania	..	6.5
Bosnia and Herzegovina	20.7	14.9
Fed. Bosnia Herzegovina	20.6	14.9
Republic Srpska	21.2	15.3
Croatia	11.4	11.7
Kosovo under UNSCR 1244	0.7	10.4
FYR of Macedonia	33.9	11.6
Montenegro	..	3.8
Serbia	3.5	3.5

60. RSOS made the user cost estimates for Serbia and, at MONSTAT's invitation, it also made the user cost estimates for Montenegro. It argues that in neither case are the estimates of intermediate consumption too low. True, it has been rigorous in its interpretation of what constitutes regular repair and maintenance - excluding all expenditures that are final expenditures - but not overly so: the estimates reflect reality. Economic conditions in Montenegro and Serbia during the 1990s and the subsequent ongoing period of transition have caused owner-occupiers to neglect regular repair and maintenance with only essential repair and maintenance being carried out.<sup>1</sup> In addition, when they do undertake repair and maintenance, owner-occupiers have a preference for the types of repair and maintenance that fall under capital formation.

## **Annex 4**

### **User cost approach: Guidelines**

#### **Introduction**

1. The standard procedure recommended in the SNA for owner-occupied dwellings is to assume that the rents that would be paid are the same as the rents actually paid for similar dwellings. But the standard procedure cannot always be applied. This is the case where so few dwellings are rented that rents actually paid cannot be regarded as typical. For example, in some countries, most of the dwellings available for rent are occupied by foreigners or by employees of government or large public enterprises at rents which cannot be regarded as representative, while in other countries, dwellings may only be available for rent in the capital city or other principal urban areas.

2. The following rules are recommended for deciding when the standard approach should not be used:

---

<sup>1</sup> RSOS also points out that, in the pre-transition period, occupiers or "tenants" of multi-occupied buildings did not consider themselves responsible for the maintenance and repair of common or communal areas in the building (this was the responsibility of the "landlord" or "state") and these areas were neglected. This mentality still prevails to some degree even though the "tenants" are now "owners". This too helps to explain the low expenditure on regular maintenance and expenditure.

- less than 25 per cent of all dwellings in the country are actually rented;
  - more than half of the rented dwellings are occupied by foreigners paying high rents or by government or other employees paying low rents; and
  - rented dwellings are not evenly distributed over all parts of the country.
3. When the standard procedure cannot be used, expenditure on dwellings is estimated by the **user cost approach**. The user cost approach consists of estimating each of the costs that owners of dwellings would need to take into account in fixing a market rent if they decided to rent their dwellings to other people rather than to live in them themselves. These costs (with 1993 SNA codes in brackets) are:
- Intermediate consumption (P2).
  - Other taxes on production (D29).
  - Consumption of fixed capital (K1).
  - Net operating surplus (B2).
4. The sum of consumption of fixed capital and the net operating surplus can be described as the *capital service* provided by the dwelling and the net operating surplus is sometimes referred to as the *cost of capital*. Here, however, the terms used are those that are used in a national accounts context.
5. Table 1 is in the form of a worksheet and lists the various data items that are required to impute expenditure on owner occupied dwelling services by the user cost approach.
6. The Table is completed for each type of owner-occupied dwelling that can be separately distinguished in the housing statistics available in each country. At a very minimum it would be desirable to distinguish:
- Single-family dwellings (houses or villas).
  - Apartments below a certain floor space (such as below 30 m<sup>2</sup>).
  - Apartments above a certain floor space (such as 30 m<sup>2</sup> or more).
7. The main difficulties in applying the user cost approach as outlined in Table 1 are:
- estimating the **stock of owner-occupied dwellings**, which is required to calculate both consumption of fixed capital (UC 09) and the net operating surplus (UC 14);
  - calculating **consumption of fixed capital** (UC 09) once the stock has been estimated; and
  - choosing the **rate of return** (UC 13) to be applied to the current value of the stock of owner-occupied dwellings (UC 12) to calculate the net operating surplus (UC 14).
8. Each of these problems is now considered in turn.

### **Stock of owner-occupied dwellings**

9. The standard procedure for estimating the stock of a capital asset is the perpetual inventory method (PIM). The PIM requires long time series on gross fixed capital formation (GFCF) and on prices of capital assets as well as assumptions about the average service lives of assets and about how retirements of assets are distributed around this average. Most countries, however, do not have capital stock estimates or the means to derive them by the PIM so it is necessary to consider an alternative method.
10. Table 2 is a worksheet that can be used to estimate the value at current market prices of the stock of each type of owner-occupied dwelling. It is designed for countries that only have information from a recent population census on the number of owner-occupied dwellings classified by a few broad types of dwellings.
11. The first step is to draw up a classification of dwellings which distinguishes between the main types of owner-occupied dwellings in the country. The stocks of owner-occupied dwellings will then be estimated separately for each type. A simple three-way classification – single family dwellings (houses or villas) and two size classes of apartments - was suggested above.

### **Consumption of Fixed Capital**

12. Countries that estimate stocks of dwellings using the PIM will already have estimates of consumption of fixed capital. For countries that do not do so, some other method must be used and one alternative method is described here.

13. When the PIM is used, the commonest way of calculating consumption of fixed capital is to assume *straight-line depreciation* – equal fall in value of the asset each year of its service life – and to assume that retirements of assets are distributed around the average service life according to a *bell-shaped mortality function*<sup>2</sup>. This method of calculating consumption of fixed capital can be described as “straight-line depreciation with a bell-shaped mortality function”.

14. This method can be approximated by a simpler procedure in which annual consumption of fixed capital is calculated as a constant fraction of the value of the stock of dwellings at current market prices. This method of calculating consumption of fixed capital is described as “geometric depreciation with no mortality function”.

15. Although it is only an approximation to *straight-line depreciation with a bell shaped mortality function*, *geometric depreciation with no mortality function* offers the important advantage that it does not require countries to have a long time-series of gross fixed capital formation in order to apply the mortality function.

16. For countries that have used the approach described in Table 2 to estimate the stock of owner-occupied dwellings, *geometric depreciation with no mortality function* is the only feasible method. Consumption of fixed capital (CFC) is obtained by multiplying the mid-year value of the net capital stock by the *depreciation rate*.

17. The *depreciation rate* used for geometric depreciation is usually written as  $D/L$ , where  $D$  is the “declining balance rate” and  $L$  is the average service life of the assets.  $D$  is usually assumed to lie between 1 and 3 and it has been found that for dwellings in Europe and North America, a value of 1.6 produces estimates of consumption of fixed capital that are similar to those that are obtained using straight-line depreciation with a bell-shaped mortality function. In the absence of information to the contrary, it is here recommended that  $D$  be set at 1.6. Thus, for example, if the mid-year net value of the stock of a particular type of owner-occupied dwelling is 4000, and if the average service life for that type of dwelling is 70 years, CFC is obtained as  $4000 \times (1.6/70) = 91$ .

18. Table 3 is a worksheet for calculating CFC. As was explained above with regard to the stock of owner-occupied dwellings, the calculations are made separately for each type of dwelling for which separate information is available. Note that for calculating consumption of fixed capital, the capital stock must exclude the value of land underlying dwellings.

#### Rate of return used to estimate net operating surplus

19. Economists assume that people acquire capital assets because the net operating surplus that they expect to earn is at least as high as the interest that they could earn by investing in a financial asset. This reasoning applies whether the capital asset is a factory building, a machine, a truck or, as here, a dwelling.

20. In practice, there are many interest rates that could reasonably be used as the rate of return to estimate the net operating surplus. In countries where there is a well established and widely used system of housing loans, the rate charged on these loans is the best one to use. Where there is no such system in place, the rate on long term (8 years or more) corporate or government bonds could be used. Note that all rates should be on newly issued debt and not the average rate paid on outstanding debt, which reflects rates existing in prior years.

21. In countries where financial markets are less developed, none of these alternatives may be feasible. In this case it is recommended that a standard annual rate of return of 2.5% should be used. This means that the net operating surplus will be calculated as 0.025 times the current market value of the stock of owner-occupied dwellings.

**Table 1: Worksheet for estimating expenditure on owner-occupied dwelling services by the user-cost method**

Item No.	Description of the item	Value
<b>Intermediate consumption</b>		
UC 01	Expenditure on maintenance and repair of owner-occupied dwellings	
UC 02	Gross insurance premiums paid on owner-occupied dwellings	

<sup>2</sup> The mortality function determines what percentage of assets installed in a given year are retired in each of the years prior to the average, in the year when they reach their average service life, and in each year following the average service life. Several different functions are used for this purpose including Weibull, Winfrey and the log-normal distributions. For details see *Measuring Capital: Measurement of Capital Stocks, Consumption of Fixed Capital and Capital Services*, OECD, Paris, 2001.

UC 03	Insurance claims paid to owners (minus)	
UC 04	Net insurance premiums paid by owners. (UC 02) – (UC 03)	
UC 05	Total intermediate consumption. (UC 01) + (UC 04)	
<b>Other taxes on production</b>		
UC 06	Taxes paid by owners on dwelling services	
UC 07	Taxes paid by owners on the value of owner-occupied dwellings and their associated land	
UC 08	Total taxes paid by owners. (UC 06) + (UC 07)	
<b>Consumption of fixed capital</b>		
UC 09	Consumption of fixed capital on owner-occupied dwellings at current prices (excluding land)	
<b>Net operating surplus</b>		
UC 10	Current market value of the stock of owner occupied dwellings at the beginning of the year (including land)	
UC 11	Current market value of the stock of owner occupied dwellings at the end of the year (including land)	
UC 12	Current market value of the stock of owner occupied dwellings at mid-year (including land) ((UC 10) + (UC 11))/2 or (K6 + K8)	
UC 13	Rate of return on owner-occupied dwellings (including land) in percent per annum.	
UC 14	Net operating surplus. (UC13) * (UC12)/ 100	
<b>Expenditure on owner-occupied dwelling services</b>		
UC 15	Expenditure on owner-occupied dwelling services. (UC05) + (UC 08) + (UC09) + (UC14)	
<b>Notes to Table 1</b>		
<p><b>UC 01:</b> Expenditures on maintenance and repair are expenditures on replacing or repairing parts of the dwelling that are broken or dilapidated; repairing the roof, replacing window frames, painting the outside of the building are examples. Maintenance and repair expenditures do not extend the service lives of dwellings beyond their previously expected lifetimes and do not involve enlarging the dwelling. (Expenditures of this kind are treated as gross fixed capital formation in the SNA).</p> <p>Information about expenditures on maintenance and repairs is usually obtained from a household expenditure survey although some countries estimate them from a supply/use table. In some countries expenditures on maintenance and repair of dwellings are incorrectly shown as a separate component of final consumption expenditure of households. When the user cost approach is used, they must be included as part of rents and not as a separate expenditure item. Note also that when countries use the standard procedure, rents will already include these expenditures and showing them as a separate item of household consumption expenditure will lead to double counting.</p> <p><b>UC 02:</b> Gross insurance premiums on dwellings should only include insurance on the dwellings themselves and not on their contents; premiums for the latter are a separate item of household final consumption expenditure. When data are available only for the total of both kinds of insurance, the necessary split between the two can be estimated as being proportional to the relative values of the stock of dwellings and the contents.</p>		

**Notes to Table 1 (contd.)**

**UC 03:** Insurance claims include only the value of the claims for damage to the dwelling itself. As in item UC 02, when data are only available on the total of claims paid on the dwellings themselves and claims paid on their contents, the necessary split between the two can be estimated as being proportional to the relative values of the stock of owner-occupied dwellings on the one hand and the contents of the dwelling on the other.

In some countries it is not customary to insure dwellings so both UC 02 and UC 03 will be zero. Even in countries where dwellings are insured, net premiums usually form less than one per cent of intermediate consumption.

**UC 06:** Some countries charge taxes on the imputed value of the dwelling services that individuals derive from owning the dwellings they reside in. Taxes on dwelling services are the value of any such taxes. Any subsidies that owner-occupiers receive to assist them in paying current housing expenses, such as government subsidisation of mortgage payments, should be included here as negative taxes.

**UC 07:** Taxes on dwellings and land are taxes paid on the value of the dwelling units themselves and the land on which they are located. These taxes are often called "property taxes".

**UC 09:** Consumption of fixed capital on the stock of owner-occupied dwellings is measured at current prices and is sometimes called *depreciation at current replacement cost*. Estimates of consumption of fixed capital should be obtained from estimates of the stock of owner-occupied dwellings valued in current prices. The stock estimates are preferably obtained by the Perpetual Inventory Method (PIM) which is described in detail in the OECD Manual, *Measuring Capital: Measurement of Capital Stocks, Consumption of Fixed capital and Capital Services* (Paris, 2001). However, many countries that do not have sufficient data to apply the PIM and Table 2 below is a worksheet that gives a method for deriving an approximate estimate of the stock of owner-occupied dwellings that can be used by these countries.

**UC 10, UC 11:** The value of the stock of owner-occupied dwellings represents the value of the net (or "depreciated") stock of these dwellings valued at current market prices. Table 1 assumes that the estimates of the stock of owner-occupied dwellings refer to the end of each year and so successive end-year estimates must be averaged to obtain mid-year estimates. The procedure shown in Table 2 produces an estimate of the stock for the middle of the year so that this averaging procedure is not required.

Note that the stock of dwellings used here must include the estimated value of the land underlying the buildings. Table 2 below is a worksheet to calculate both the value of the dwellings themselves and the land on which they are situated.

**UC 13:** The choice of the rate of return used to calculate the net operating surplus is discussed below.

**UC 14:** The net operating surplus of owner-occupied dwellings is calculated by applying the rate of return to the mid-year, current value of the stock of dwellings.

**Table 2: Worksheet for estimating the stock of dwellings at current market prices for countries that cannot apply the perpetual inventory method**

Item No.	Description of the item	Value
K 1	Number of owner-occupied dwelling units at the time of the most recent census	
K 2	Growth rate of owner-occupied dwellings between the last census and the middle of the current year	
K 3	Estimated number of owner-occupied dwellings in the middle of the current year. $((K1)*(K 2))$	
K 4	Average price of newly-constructed dwellings, excluding land, in the current year	
K 5	Average net value (i.e. after deducting accumulated depreciation) of a dwelling, excluding land, in the current year. $((K 4)*(1-A/L))$ See explanation below.	
K 6	Value at current market prices of the stock of owner-occupied dwellings, excluding land. $((K 3)*(K 5))$	
K 7	Ratio of the value of land to the average net value of dwellings (excluding land), in the current year	
K 8	Value at current market prices of land underlying dwellings( $(K6) * (K7)$ )	

**Notes to Table 2**

**K 1:** Population censuses invariably collect some information on dwellings – at a minimum the number of owner-occupied dwellings with some indications of their physical characteristics. The more recent the Census, the better will be the estimate of the stock of dwellings for the current year. Many countries also carry out some kind of *Living Standards* survey and these usually collect detailed statistics on the type of structure and the facilities contained in dwellings.

**Notes to Table 2 (contd.)**

**K 2:** The growth rate in the number of owner-occupied dwellings since the last census could be derived from a number of sources. These include gross fixed capital formation (GFCF) statistics, building permits issued, and administrative data on completion and destruction of buildings. In the absence of any information of this kind, it is reasonable to assume that the stock of owner-occupied dwellings grows at the same rate as the population.

**K 4:** Information on prices can be obtained from various sources including real estate agents, property developers, and advertisements in journals and magazines that specialise in sales of dwellings. If these sources are used it will be necessary to adjust the prices downwards by subtracting the value of the land underlying the buildings, since the prices must refer only to the physical structure. An alternative is to obtain information on the costs of new buildings from construction companies or from "public works" departments that in some countries build dwellings for government employees. If a cost approach is used, the cost figure will need to be adjusted to market prices by adding the estimated profit margins. The advantage, however, is that the cost estimates will refer only to the physical structure and will exclude the cost of the underlying land.

**K 5:** Since K 4 refers to the price of a newly constructed dwelling, this price needs to be adjusted downwards so that it approximates the price of a dwelling of average age. To do this it is necessary to make an assumption about how the prices of dwellings decline as they grow older. The simplest assumption, and the one recommended here, is to assume that the prices of dwellings decline by the same amount each year reaching a zero price in the last year of their life. With this assumption, the price of a dwelling of average age ( $P_{average}$ ) will equal the new price ( $P_{new}$ ) times the ratio of the remaining years that the dwelling of average age ( $A$ ) will continue to exist to the expected service life ( $L$ ), that is.

$$P_{average} = P_{new} \left( \frac{L - A}{L} \right) \text{ or } \left( 1 - \left( \frac{A}{L} \right) \right) \quad [1]$$

Intuitively, one would expect that if the stock of dwellings is constant because the number of new dwellings constructed each year is the same as the number of old dwellings demolished each year, the average age will be half of the average service life – i.e. ( $P_{average}$ ) will be half of ( $P_{new}$ ). In the usual case, however, stocks of dwellings are not constant. When stocks are growing or falling, the average age of the dwellings in a stock ( $A$ ) can be written as:

$$A = \frac{\sum_i^L i(1+r)^{L-i}}{\sum_i^L (1+r)^{L-i}} \quad [2]$$

where:

- $L$  is the average service life of dwellings,
- $r$  is the annual rate of growth in the stock of dwellings, and
- $i$  is the age of dwellings constructed in a given year and takes the values of  $1, 2, 3, \dots, L$

Note that when a stock of dwellings is stable (that is when  $r = 0$ ), the numerator is the sum of the first  $L$  digits, that is  $\frac{L(L+1)}{2}$  and the denominator is  $L$  so that [2] reduces to  $(L+1)/2$ . This is the mid-point of the digits from  $1$  to  $L$  and confirms the intuitive result mentioned above.

If the stock is growing, the average age will be less than the mid-point because the number of younger dwellings will exceed the number of older dwellings. (And *vice versa* if the stock is declining.) When the percentage of new dwellings is growing, the average price will also rise and vice versa if the percentage of older dwellings is rising.

If the stock of dwellings is thought to be growing, the value of  $A$  should be calculated with  $r$  set at the rate used to calculate K 2, and  $L$  set at the estimated average service life of dwellings. The value of the stock of dwellings (K 6) is then obtained as: (Number of dwellings in the stock (K 3)) *times* (Price of a newly constructed dwelling (K 4)) *times*  $(1 - A/L)$ .

**Notes to Table 2 (contd.)**

Table 2A gives the values of the adjustment factor –  $1-(A/L)$  – for values of L commonly assumed for dwellings and rates of annual growth in the housing stock from -1% to + 3%.

<b>Table 2A: Values of <math>(1-(A/L))</math></b>					
Average service life of dwellings	Annual growth rate of the stock of dwellings				
	-1%	zero	1%	2%	3%
60 years	0.442	0.492	0.541	0.588	0.632
70 years	0.435	0.493	0.550	0.605	0.654
80 years	0.427	0.494	0.559	0.621	0.675

**K7:** In order to calculate consumption of fixed capital, the estimated value of the stock of dwellings must exclude the value of the land on which the dwellings are situated, because there is no consumption of fixed capital is calculated in respect of land. However, for calculating the net operating surplus it is necessary to include the value of the land together with the dwellings because the owner's total investment covers both. For this reason, two estimates of the stock of dwellings are required – one with, and one without, the value of land.

Estimates of the average ratio of the value of land to the average value of dwellings (excluding land) can be obtained from sources such as realtors (estate agents) or official records of land values. Some countries may be able to borrow ratios estimated from neighbouring countries which have similar population densities and housing structures.

In the United States, land values represent about one-third of the value of the building itself. Ratios are higher in Western Europe where the amount of land available for constructing dwellings is more limited but they are likely to be lower than one-third in less densely populated countries. In some countries, land cannot be owned and plots are granted for families to construct their dwellings. In such cases, the land value is zero since it cannot be traded and so has no commercial value to the owner of the dwelling.

**Table 3: Worksheet for estimating consumption of fixed capital of owner-occupied dwellings at current prices**

Item No.	Description of the item	Value
CFC 1	Mid-year current market value of the stock of owner-occupied dwellings, excluding land.	
CFC 2	Estimated service life of owner-occupied dwellings (in years)	
CFC 3	Depreciation rate for owner-occupied dwellings. $1.6/(CFC 2)$	
CFC 4	Consumption of fixed capital formation of owner-occupied dwellings in current market prices. $(CFC 1) * (CFC 3)$	

**Notes to Table 3**

**CFC 1:** The current market value of the stock of owner-occupied dwellings is taken from K 6 in Table 2 above. Note that K6 is the value of the dwelling stock excluding the value of the underlying land.

**CFC 2:** The average service life is the number of years that dwellings of this type are expected to remain in use from the year of construction until the dwelling is demolished. The estimate of the average service life is important because it effectively determines the depreciation rate. Estimates of service lives for dwellings vary widely. European countries have generally used service lives of between 50 and 90 years. In the absence of any reliable information, an average service life of 70 years can be used.

Population Censuses usually collect information on the age of dwellings and this can be used to estimate life expectancies.

**CFC 3:** A "declining balance" rate of 1.6 is to be used, so that the depreciation rate is  $1.6 / (CFC 2)$ . As noted above, a value of 1.6 has been found to provide a plausible pattern of CFC for dwellings in Europe and North America. With a declining balance rate of 1.6 and an average service life of 70 years, the depreciation rate will be  $1.6 / 70 = 0.023$  so that CFC will be calculated as 0.023 times the current market value of the stock of owner-occupied dwellings.
